20/8/26 Exp: 4 Sliding window protocal

Aim:

Write a program to implement flow cont at data sink layer using sliding wind protocal simulate the flow of frame fro one node to another.

Code:

sender program:

```
import time
msg = input ("Message")
w = int (input ("window size = "))
i = 0
while i < len (msg):
if = ( if " {j+1}, {msg [j]}" {0} j in
range (i, min (i+w, len (msg)))]
print ("sending", if)
open ("sender_buffer", "w"), wrik
("/n", join (if))
time. sleep (2)
ack = open ("Reciver_buffer"). read().
strip ()
print (ack)
if ack. count ("ACK").
i = int (ack. split () [1])
```

Recvier program:

```
import time
e = 1
while true:
if = open ("sender_buffer"). read().
```

```
if of:
    print ["Received", of)
    ok = all (int (*.split)", if [0]) == e+i
    if or i, b in enumerate (if))
if ok:
    e+ = len (if)
a = of "Ack {e-1}"
else:
a = if "NACK {e}"
open ("Receiver_Beep; "w"), write (w,
print (a)
time sleep (2)
```

Input:

message: HELLO

window size: 3

Output:

sending: ['1,H', '2,E', '3,L']

ACK 3

sending - ['4;L', '5,0]

ACK 5

All frames sent successfully

Result: Thus the program is executed successfully and output is verified.
